| 2 | An example | | 1 | |
| | 2.1 | BitPhylogeny | 1 | |
| | 2.2 | Baseline methods | 4 | |
| 3 | Reproduce figure 3B | | 8 | |
| 4 | Reproduce figure 3C | | 10 | |

1 Installation

The BitPhylogeny packages depends on several python and R packages. The first step is to make sure the following the packages are installed. * python: numpy, scipy, scikit-learn: http://scikit-learn.org/stable/, rpy2: http://rpy.sourceforge.net/ * R: rPython, mcclust, e1071, igraph, gplots, riverplot

Secondly, clone the BitPhylogeny repository

```
git clone git@bitbucket.org:ke_yuan/bitphylogeny.git
cd bitphylogeny
```

The third step is install the BitPhylogeny python package. To do this, navigate into the python directory and run the following

```
cd python
sudo python setup.py install
```

Finally, install the R package

R CMD INSTALL bitphylogenyR_0.1.tar.gz

2 An example

2.1 BitPhylogeny

We use an example dataset

```
library('bitphylogenyR')
```

```
## Loading required package: rPython

                  0
                    0
```

Note that the last column is set to be the true cluster label of each data point. We separate the data and its label.

```
x <- tmp[,-dim(tmp)[2]]
true_label <- tmp[,dim(tmp)[2]]</pre>
```

Run the BitPhylogeny analysis as the following

0 1

```
bitphyloR( example_file, './output', T, 20, 10, 2)
```

NULL

5

0 0 0 0 0 0

0 0 0 0 0

The program saves the results in the directory 'output'.

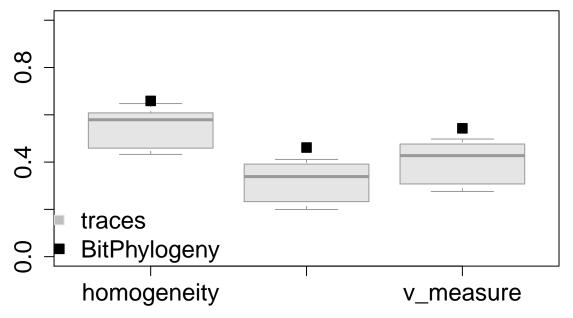

```
dir('./output', recursive=T)
```

```

## [17] "sample_data.csv/treescripts/tree-freq.csv"
```

The clustering performance is assessed by the V-measure. In addition, the label trace is summarised by the maximum posterior expected adjusted Rand method.

NULL

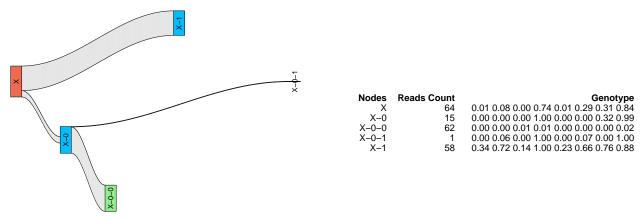

We can visualise the results in the following way

The resulting trees are stored in the treescripts directory. The file tree-freq contains the appearance frequency of each tree in the folder.

```
treefreq <- read.csv('./output/sample_data.csv/treescripts//tree-freq.csv')
treefreq</pre>
```

plot_sankey_mft('./output/sample_data.csv/treescripts//tree-freq.csv')

Alternatively, the .gdl files can be visualised with the aisee3 software.

2.2 Baseline methods

The baseline methods are consisted of clustering followed by minimum spanning tree construction.

2.2.1 Hierarchical clustering

We first compute the Jacard distance matrix for the sequences.

```
dis <- dist(x, 'binary')</pre>
```

Then, we use the R function hclust to perform hierarchical clustering based on the previously computed distance matrix.

```
hc <- hclust(dis)
hc

##
## Call:
## hclust(d = dis)
##
## Cluster method : complete
## Distance : binary
## Number of objects: 200</pre>
```

The resulting labels of each data point is obtained with the function cutree. The function takes the output of hclust and the number of desired clusters k. In this case, we set k to be 7.

When there is a range of cluster number hypothesis, we compute a list of possible labels.

```
K <- seq(2,14,1)
hc_cand <- lapply(K, function(ii) cutree(hc, ii) )</pre>
```

Each of these hypothesis is evaluated by the Silhouette score. The one with the highest score is chosen as the clustering result.

```

                                     7
                                        7
                                            7 11 11 11 11 11 11
                                                                    9
                                                                       9
## [162]
          7
              7
                                                                           9
  [185] 13 13 13 14 14 14 14 14 14
                                           4 5 11 11 11 14
```

Once the label is computed, we compute the genotype of each cluster as the following

```
clone <- sapply(unique(hc_label), function(i) which(hc_label==i) )
n <- length(clone)
hc_genotype <- matrix(0, n, dim(x)[2])
for (i in 1:n){
   idx <- clone[[i]]
   if ( length(idx)==1 ){
      hc_genotype[i,] <- as.matrix(x[idx,])
   }else{
      hc_genotype[i,] <- as.numeric( colMeans(as.matrix(x[idx,])) > 0.5 )
   }
}
hc_genotype
```

```

                                     1
```

Finally, we put the above steps into a function which gives the label and genotype estimates.

```
get_label_hc
```

```
## function (x, K)
## {
##
       dis <- dist(x, "binary")</pre>
##
       hc_cand <- lapply(K, function(ii) cutree(hclust(dis), ii))</pre>
##
       hc_silhouette_res <- sapply(1:length(K), function(ii) summary(silhouette(hc_cand[[ii]],
##
            dis))$avg.width)
##
       idx <- which.max(hc_silhouette_res)</pre>
##
       hc_label <- hc_cand[[idx]]</pre>
       clone <- sapply(unique(hc_label), function(i) which(hc_label ==</pre>
##
##
            i))
##
       n <- length(clone)</pre>
       genotype <- matrix(0, n, dim(x)[2])</pre>
##
       for (i in 1:n) {
##
            idx <- clone[[i]]</pre>
##
##
            if (length(idx) == 1) {
##
                genotype[i, ] = as.matrix(x[idx, ])
            }
##
            else {
##
                genotype[i, ] = as.numeric(colMeans(as.matrix(x[idx,
##
##
                     ])) > 0.5)
##
            }
##
       }
##
       return(list(hc_label = hc_label, hc_genotype = genotype))
## }
## <environment: namespace:bitphylogenyR>
```

2.2.2 K-centroids clustering

The k-centroids methods uses the same distance matrix compute above.

```
kc = pam(dis, 7)
kc
```

```
## Medoids:
## ID

## [1,] 65 65

## [2,] 194 194

## [3,] 158 158

## [4,] 195 195

## [5,] 127 127

## [6,] 172 172

## [7,] 135 135

## Clustering vector:
```

```
##
  ##
 ## [176] 3 3 3 7 7 7 7 7 6 6 6 6 6 2 2 2 2 2 2 4 3 2 2 2 2
## Objective function:
##
  build
     swap
## 0.05225 0.05225
##
## Available components:
## [1] "medoids"
        "id.med"
             "clustering" "objective"
